## 1 Introduction and the results

For any fixed  $q \in \mathbb{C}$  with  $|q| > 1$  and  $z \in \mathbb{C}$ , the  $q$ -logarithmic function  $L_q(z)$  and the  $q$ -exponential  $E_q(z)$  are defined by

$$L_q(z) := \sum_{n=1}^{\infty} \frac{z^n}{q^n - 1} = \sum_{n=1}^{\infty} \frac{z}{q^n - z} \quad (|z| < |q|),$$

$$E_q(z) := 1 + \sum_{n=1}^{\infty} \frac{z^n}{(q-1) \cdots (q^n - 1)} = \prod_{n=1}^{\infty} \left(1 + \frac{z}{q^n}\right),$$

respectively. Bézivin [2] showed that the numbers  $1, E_q^{(k)}(\alpha_i)$  ( $i = 1, \dots, m, k = 0, 1, \dots, l$ ) are linearly independent over  $\mathbb{Q}$ , where  $q \in \mathbb{Z} \setminus \{0, \pm 1\}$  and  $\alpha_i \in \mathbb{Q}^\times$  satisfy  $\alpha_i \neq -q^\mu$  and  $\alpha_i \neq \alpha_j q^\nu$  for all  $\mu, \nu \in \mathbb{Z}$  with  $\mu \geq 1$  and  $i \neq j$ . This implies that

$$\sum_{n=1}^{\infty} \frac{1}{q^n + \alpha} \notin \mathbb{Q},$$

where  $q \in \mathbb{Z} \setminus \{0, \pm 1\}$  and  $\alpha \in \mathbb{Q}^\times$  with  $\alpha \neq -q^i$  ( $i \geq 1$ ). Under the same conditions on  $q$  and  $\alpha$ , Borwein [3], [4] obtained irrationality measures for the numbers  $\sum_{n=1}^{\infty} 1/(q^n + \alpha)$  and  $\sum_{n=1}^{\infty} (-1)^n/(q^n + \alpha)$ . These results include the irrationality of  $L_2(1) = \sum_{n=1}^{\infty} 1/(2^n - 1)$  proved by Erdős [10]. Furthermore, Bundschuh and Väänänen [6], and Matala-Aho and Väänänen [11] obtained quantitative irrationality results for the values of the  $q$ -logarithm both in the Archimedean and  $p$ -adic cases. In [7], Duverney generalized certain results obtained by Borwein [3], [4], and Bundschuh and Väänänen [6]. Recently, Van Assche [15] gave irrationality measures for the numbers  $L_q(1)$  and  $L_q(-1)$  by using little  $q$ -Legendre polynomials. In this paper, we prove irrationality results for certain Lambert series, which in particular implies the linear independence of the numbers  $1, L_q(1), L_q(-1)$  with  $q \in \mathbb{Z} \setminus \{0, \pm 1\}$  by developing Borwein's idea in [4].

Let  $R_n$  be a binary recurrence defined by

$$R_{n+2} = A_1 R_{n+1} + A_2 R_n \quad (n \geq 0), \quad A_1, A_2 \in \mathbb{Q}^\times, \quad R_0, R_1 \in \mathbb{Q}.$$

André-Jeannin [1] proved for some  $R_n$  the irrationality of the value of the function  $f(x) = \sum_{n=1}^{\infty} x^n/R_n$  at a nonzero rational integer  $x$  in the disk of convergence of  $f$ , which gave the first proof of the irrationality of the numbers  $\sum_{n=1}^{\infty} 1/F_n$  and  $\sum_{n=1}^{\infty} 1/L_n$ , where  $F_n$  and  $L_n$  are Fibonacci numbers and Lucas numbers, respectively. Prévost [13] extended this result to any rational  $x$  in the domain of meromorphy of  $f$ . Recently, Matala-aho and Prévost [12] obtained for some type of  $R_n$  irrationality measures for the number  $\sum_{n=1}^{\infty} \gamma^n/R_{an}$ , where  $\gamma$  belongs to an imaginary quadratic field, and  $a > 0$  is an integer. We will prove for some  $R_n$  the irrationality of the numbers  $\sum_{n=1}^{\infty} \gamma^n/R_{an+b}$  and  $\sum_{n=1}^{\infty} \gamma^n/R_{an+b}R_{a(n+1)+b}$ , where  $a > 0$ ,  $b \geq 0$  are integers and  $\gamma$  is a certain number in a real quadratic field (see Corollaries 2 and 3, below).

For an algebraic number  $\alpha$ , we denote by  $|\alpha|$  the maximum of absolute values of its conjugates and by  $\text{den } \alpha$  the least positive integer such that  $\alpha \cdot \text{den } \alpha$  is an algebraic integer. We define generalized Pisot number  $\alpha$  by algebraic integer  $\alpha$  satisfying  $|\alpha| > 1$  and  $|\alpha^\sigma| < 1$  for any  $\sigma \in \text{Aut}(\overline{\mathbb{Q}}/\mathbb{Q})$  with  $\alpha^\sigma \neq \alpha$ . We put  $\mathbb{N} = \{0, 1, 2, \dots\}$ .

**Theorem 1.** *Let  $K$  be either  $\mathbb{Q}$  or an imaginary quadratic field. Assume that  $q$  is an integer in  $K$  with  $|q| > 1$  and  $\{a_n\}$  a periodic sequence in  $K$  of period two, not identically zero. Then*

$$\theta = \sum_{n=1}^{\infty} \frac{a_n}{1 - q^n} \notin K.$$

**Corollary 1.** *Let  $q \in \mathbb{Z}$  with  $|q| \geq 2$  and  $\{a_n\}, \{b_n\}$  be periodic sequences in  $\mathbb{Q}$  of period two, not identically zero. Then the numbers*

$$1, \quad \sum_{n=1}^{\infty} \frac{a_n}{q^n - 1}, \quad \sum_{n=1}^{\infty} \frac{b_n}{q^n - 1}$$

*are linearly independent over  $\mathbb{Q}$  if and only if  $\{a_n\}$  and  $\{b_n\}$  are linearly independent over  $\mathbb{Q}$ .*

*Proof.* This follows immediately from Theorem 1.

**Example 1.** *Let  $q \in \mathbb{Z}$  with  $|q| \geq 2$ . Then*

$$1, \quad L_q(1) = \sum_{n=1}^{\infty} \frac{1}{q^n - 1}, \quad L_q(-1) = \sum_{n=1}^{\infty} \frac{(-1)^n}{q^n - 1} = \sum_{n=1}^{\infty} \frac{-1}{q^n + 1}$$

*are linearly independent over  $\mathbb{Q}$ .*

**Theorem 2.** *Let  $q$  be a quadratic generalized Pisot number,  $\gamma$  a unit in  $\mathbb{Q}(q)$  with  $|\gamma| \leq 1$ , and  $\alpha \in \mathbb{Q}(q)^\times$  with  $(\text{den}(q^l \alpha))^4 < |q|$  for some  $l \in \mathbb{N}$ . Then*

$$\xi = \sum_{n=1}^{\infty} \frac{\gamma^n}{1 - \alpha q^n} \notin \mathbb{Q}(q),$$

*provided that  $\alpha q^n \neq 1$  for all  $n \geq 1$ .*

In the following Corollaries 2 and 3, we consider the binary recurrences  $\{R_n\}_{n \geq 0}$  defined by

$$R_{n+2} = A_1 R_{n+1} + A_2 R_n, \quad A_1, A_2 \in \mathbb{Z} \setminus \{0\}, \quad R_0, R_1 \in \mathbb{Z}.$$

We suppose that  $R_n \neq 0$  for all  $n \geq 1$ , the corresponding polynomial  $\Phi(X) = X^2 - A_1 X - A_2$  is irreducible in  $\mathbb{Q}[X]$ , and  $\Delta = A_1^2 + 4A_2 > 0$ . We can write  $R_n$  as

$$R_n = g_1 \rho_1^n + g_2 \rho_2^n \quad (n \geq 0), \quad g_1, g_2 \in \mathbb{Q}(\rho_1)^\times, \quad (1)$$

where  $\rho_1$  and  $\rho_2$  are the roots of  $\Phi(X)$ . We may assume  $|\rho_1| > |\rho_2|$ , since  $\Delta > 0$ .

For  $a, b \in \mathbb{N}$  with  $a \neq 0$ , we define

$$R(z) = \sum_{n=1}^{\infty} \frac{z^n}{R_{an+b}} \quad (|z| < |\rho_1|^a).$$

This function can be extended to a meromorphic function on the whole complex plane  $\mathbb{C}$  with poles  $\{(\rho_1^{n+1}/\rho_2^n)^a \mid n \geq 0\}$ , since

$$\sum_{n=1}^{\infty} \frac{z^n}{1 - \alpha q^n} = \sum_{m=1}^{\infty} \frac{\alpha^{-m} z}{z - q^m} \quad (|z| < |q|)$$

for any complex numbers  $q$  and  $\alpha$  with  $|q| > 1$  and  $|\alpha| \geq 1$ , and so

$$\sum_{n=1}^{\infty} \frac{z^n}{R_{an+b}} = \sum_{n=1}^i \frac{z^n}{R_{an+b}} - \frac{z^{i+1}}{g_1 \rho_1^{ai+b}} \sum_{n=0}^{\infty} \frac{(-(g_2/g_1)(\rho_2/\rho_1)^{ai+b})^n}{z - \rho_1^a (\rho_1/\rho_2)^{an}}, \quad (2)$$

where  $i$  is chosen as  $|(g_2/g_1)(\rho_2/\rho_1)^{ai+b}| < 1$ . We denote the function again by  $R(z)$ .

**Corollary 2.** Let  $R_n$  be a binary recurrence given by (1) and  $a, b \in \mathbb{N}$  with  $a \neq 0$ . Assume that  $g_1/g_2$  and  $\rho_1/\rho_2$  are units in  $\mathbb{Q}(\rho_1)$  and  $\gamma \in \mathbb{Q}(\rho_1)^\times$  is not a pole of  $R(z)$  with  $(\text{den}(\rho_1^a/\gamma))^4 < |\rho_1/\rho_2|^a$ . Then we have  $R(\gamma) \notin \mathbb{Q}(\rho_1)$ .

*Proof.* Apply Theorem 2 to the last sum in (2).

**Example 2.** Let  $F_n$  and  $L_n$  be Fibonacci numbers and Lucas numbers defined by  $F_{n+2} = F_{n+1} + F_n$  ( $n \geq 0$ ),  $F_0 = 0$ ,  $F_1 = 1$  and  $L_{n+2} = L_{n+1} + L_n$  ( $n \geq 0$ ),  $L_0 = 2$ ,  $L_1 = 1$ , respectively. Then for every  $a, b \in \mathbb{N}$  with  $a \neq 0$ ,

$$\sum_{n=1}^{\infty} \frac{1}{F_{an+b}}, \quad \sum_{n=1}^{\infty} \frac{(-1)^n}{F_{an+b}}, \quad \sum_{n=1}^{\infty} \frac{1}{L_{an+b}}, \quad \sum_{n=1}^{\infty} \frac{(-1)^n}{L_{an+b}} \notin \mathbb{Q}(\sqrt{5}).$$

André-Jeannin[1] proved that each of these numbers is irrational. We remark that the numbers  $\sum_{n=1}^{\infty} 1/F_{2n+1}$  and  $\sum_{n=1}^{\infty} 1/L_{2n}$  are transcendental (cf. [8], [9]).

**Example 3.** Let  $F_n$  be Fibonacci numbers. Then for every  $a, b \in \mathbb{N}$  with  $a \neq 0$ ,

$$\sum_{n=1}^{\infty} \frac{1}{F_{(2a-1)n+b} F_{(2a-1)(n+1)+b}}, \quad \sum_{n=1}^{\infty} \frac{(-1)^n}{F_{2an+b} F_{2a(n+1)+b}} \notin \mathbb{Q}(\sqrt{5}).$$

The same holds for Lucas numbers. We put

$$T_l := \sum_{n=1}^{\infty} \frac{1}{F_n F_{n+l}}, \quad T_l^* := \sum_{n=1}^{\infty} \frac{(-1)^n}{F_n F_{n+l}} \quad (l \geq 1).$$

Then Brousseau [5] and Rabinowitz [14] proved that

$$T_{2l} = \frac{1}{F_{2l}} \sum_{n=1}^l \frac{1}{F_{2n-1} F_{2n}}, \quad T_{2l+1} = \frac{1}{F_{2l+1}} \left( T_1 - \sum_{n=1}^l \frac{1}{F_{2n} F_{2n+1}} \right),$$

$$T_l^* = \frac{1}{F_l} \left( \frac{1 - \sqrt{5}}{2} l + \sum_{n=1}^l \frac{F_{n-1}}{F_n} \right),$$

so that  $T_{2l} \in \mathbb{Q}$  and  $T_l^* \in \mathbb{Q}(\sqrt{5}) \setminus \mathbb{Q}$  for all  $l \geq 1$ . We see that  $T_{2l+1} \notin \mathbb{Q}(\sqrt{5})$  for all  $l \geq 0$ , since the first sum in this example with  $a = 1, b = 0$  implies

$$T_1 = \sum_{n=1}^{\infty} \frac{1}{F_n F_{n+1}} \notin \mathbb{Q}(\sqrt{5}).$$

## 2 Lemmas

For the proof of theorems, we prepare some lemmas. Let  $\{a_m\}_{m \geq 1}$  be a periodic sequence of complex numbers of period two, not identically zero. We put

$$\theta = \sum_{m=1}^{\infty} \frac{a_m}{1 - q^m},$$

where  $q \in \mathbb{C}$  with  $|q| > 1$ . We start with the integral

$$F_n(q) = \frac{1}{2\pi i} \int_{|t|=1} \frac{(-1/t) \prod_{k=1}^{2n} (1 - q^k/t)}{\prod_{k=1}^n (1 - q^{2k}t)} \sum_{m=1}^{\infty} \frac{a_m}{1 - q^m/t} dt, \quad (3)$$

which is a variant of that used by Borwein [4]. We note that the integrand is meromorphic in  $t$  provided  $|q| > 1$ . We use the notations

$$[n]_q! := \frac{(1 - q^n)(1 - q^{n-1}) \cdots (1 - q)}{(1 - q)^n}, \quad [0]_q := 1,$$

$$\begin{bmatrix} n \\ i \end{bmatrix}_q := \frac{[n]_q!}{[i]_q! [n-i]_q!} \in \mathbb{Z}[q].$$

In what follows, we denote  $c_1, c_2, \dots$  positive constants independent of  $n$ .

**Lemma 1.**

$$\begin{aligned} F_n(q) &= \sum_{i=1}^n \frac{\prod_{k=1}^{2n} (1 - q^{k+2i})}{\prod_{\substack{k=1 \\ k \neq i}}^n (1 - q^{2k-2i})} \left( \theta - \sum_{m=1}^{2i} \frac{a_m}{1 - q^m} \right) \\ &\quad - \frac{1}{(2n-1)!} \left( \prod_{k=1}^{2n} (t - q^k) \prod_{k=1}^n (1 - q^{2k} t)^{-1} \sum_{m=1}^{\infty} \frac{a_m}{t - q^m} \right)^{(2n-1)} \Big|_{t=0} \end{aligned} \quad (4)$$

*Proof.* This can be proved by using the residue theorem similarly as the proof of Lemma 1 in [4].

We put  $D_n(q) := \prod_{k=n+1}^{2n} (1 - q^{2k})$ . Then we have

$$|D_n(q)| \leq c_1 |q|^{3n^2+n}. \quad (5)$$

**Lemma 2.**

$$D_n(q)F_n(q) = A_n(q)\theta + B_n(q), \quad (6)$$

where  $A_n(q), B_n(q) \in \mathbb{Z}[a_1, a_2, q]$ .

*Proof.* Since

$$\frac{1}{\prod_{\substack{k=1 \\ k \neq i}}^n (1 - q^{2k-2i})} = \frac{q^{i(i-1)}}{\prod_{k=1}^{i-1} (q^{2k} - 1) \prod_{k=1}^{n-i} (1 - q^{2k})},$$

we have by (4)

$$\begin{aligned} F_n(q) &= \frac{1}{\prod_{k=1}^{n-1} (1 - q^{2k})} \sum_{i=1}^n (-1)^{i-1} q^{i(i-1)} \begin{bmatrix} n-1 \\ i-1 \end{bmatrix}_{q^2} \prod_{k=1}^{2n} (1 - q^{k+2i}) \left( \theta - \sum_{m=1}^{2i} \frac{a_m}{1 - q^m} \right) \\ &\quad - \sum_{\substack{\lambda, \mu, \nu \geq 0 \\ \lambda + \mu + \nu = 2n-1}} \frac{1}{\lambda! \mu! \nu!} \left( \prod_{k=1}^{2n} (t - q^k) \right)^{(\lambda)} \Big|_{t=0} \left( \prod_{k=1}^n (1 - q^{2k} t)^{-1} \right)^{(\mu)} \Big|_{t=0} \left( \sum_{m=1}^{\infty} \frac{a_m}{t - q^m} \right)^{(\nu)} \Big|_{t=0} \end{aligned}$$

with

$$\begin{aligned} \left( \prod_{k=1}^{2n} (t - q^k) \right)^{(\lambda)} \Big|_{t=0} &= \lambda! (-1)^{2n-\lambda} \sum_{\substack{\lambda_1 + \dots + \lambda_{2n} = 2n-\lambda \\ \lambda_i = 0,1}} q^{\lambda_1 + 2\lambda_2 + \dots + 2n\lambda_{2n}}, \\ \left( \prod_{k=1}^n (1 - q^{2k}t)^{-1} \right)^{(\mu)} \Big|_{t=0} &= \mu! \sum_{\substack{\mu_1 + \dots + \mu_n = \mu \\ \mu_i \geq 0}} q^{2(\mu_1 + 2\mu_2 + \dots + n\mu_n)}, \\ \left( \sum_{m=1}^{\infty} \frac{a_m}{t - q^m} \right)^{(\nu)} \Big|_{t=0} &= -\nu! \sum_{m=1}^{\infty} \frac{a_m}{(q^{\nu+1})^m} = \nu! (a_1 q^{\nu+1} + a_2) \frac{1}{1 - q^{2(\nu+1)}}. \end{aligned}$$

Hence we get

$$\begin{aligned} F_n(q) &= \frac{1}{\prod_{k=1}^{n-1} (1 - q^{2k})} \sum_{i=1}^n (-1)^{i-1} q^{i(i-1)} \begin{bmatrix} n-1 \\ i-1 \end{bmatrix}_{q^2} \prod_{k=1}^{2n} (1 - q^{k+2i}) \left( \theta - \sum_{m=1}^{2i} \frac{a_m}{1 - q^m} \right) \\ &+ \sum_{\substack{\lambda + \mu + \nu = 2n-1 \\ \lambda, \mu, \nu \geq 0}} Q_{\lambda\mu\nu}(q) \frac{1}{1 - q^{2(\nu+1)}} \end{aligned} \quad (7)$$

with  $Q_{\lambda\mu\nu}(q)$  a polynomial in  $\mathbb{Z}[a_1, a_2, q]$  for all  $\lambda, \mu, \nu \geq 0$ . Here we note that

$$\prod_{k=1}^{2n} (1 - q^{k+2i}) \sum_{m=1}^{2i} \frac{a_m}{1 - q^m} \in \mathbb{Z}[a_1, a_2, q], \quad i = 1, 2, \dots, n,$$

and each of  $\prod_{k=1}^{n-1} (1 - q^{2k})$  and  $1 - q^{2l}$  ( $l = 1, \dots, 2n$ ) divides  $D_n(q)$  in  $\mathbb{Z}[q]$ . Therefore the lemma follows from (7).

**Lemma 3.** For large  $n$ , we have

$$0 < |F_n(q)| \leq c_3 |q|^{-3n^2 - 2n}. \quad (8)$$

*Proof.* Similarly to the proof of Lemma 4 in [4], the residue theorem applied exterior to the circle  $|t| = 1$  shows that

$$F_n(q) = \sum_{m=2n+1}^{\infty} I_m, \quad I_m = a_m \frac{\prod_{k=1}^{2n} (1 - q^{k-m})}{\prod_{k=1}^n (1 - q^{2k+m})}$$

for large  $n$ . Since  $|I_m| \leq c_2 |q|^{-n^2 - n(m+1)}$ , we get the upper bound for  $|F_n(q)|$ . Furthermore, if  $a_1 \neq 0$ , it follows that,

$$F_n(q) = a_1 \frac{\prod_{k=1}^{2n} (1 - q^{k-2n-1})}{\prod_{k=1}^n (1 - q^{2k+2n+1})} \left( 1 + \sum_{l=1}^{\infty} b_{nl} \right)$$

with

$$b_{nl} = \frac{a_{l+1}}{a_1} \prod_{k=1}^n \left( \frac{1 - q^{2k+2n+1}}{1 - q^{2k+2n+l+1}} \right) \prod_{k=1}^{2n} \left( \frac{1 - q^{k-2n-l-1}}{1 - q^{k-2n-1}} \right),$$

where  $|b_{nl}| \leq c_4 |q^{-n}|^l$ . Hence we have  $F_n(q) \neq 0$ , since  $\sum_{l=1}^{\infty} |b_{nl}| < 1$  for large  $n$ . The proof is similar in the case of  $a_1 = 0, a_2 \neq 0$ .

### 3 Proofs of Theorems

**Proof of Theorem 1.** Let  $K, q$ , and  $\{a_m\}$  be as in Theorem 1. We may suppose that  $a_1$  and  $a_2$  are integers in  $K$ . Assume that  $\theta \in K$  and let  $d = \text{den } \theta$ . Then by (5), (6), and (8), we have

$$0 < d |A_n(q)\theta + B_n(q)| \leq dc_5 |q|^{-n}$$

for large  $n$ ; which is a contradiction.

**Proof of Theorem 2.** Let  $q, \alpha$ , and  $\gamma$  be as in Theorem 2. Since

$$\sum_{m=1}^{\infty} \frac{\gamma^m}{1 - \alpha q^l q^m} = \gamma^{-l} \left( \sum_{m=1}^{\infty} \frac{\gamma^m}{1 - \alpha q^m} - \sum_{m=1}^l \frac{\gamma^m}{1 - \alpha q^m} \right) \quad (l \geq 1),$$

we can assume that  $\alpha$  is a generalized Pisot number, by replacing  $\alpha$  by  $q^l \alpha$  with suitable  $l$ . We modify Borwein's integral in [4] as follows:

$$G_n(q, \alpha, \gamma) = \frac{1}{2\pi i} \int_{|t|=1} \prod_{k=1}^{n-1} \left( \frac{1 - \alpha q^k/t}{1 - q^k t} \right) \frac{-1/t}{1 - q^n t} \sum_{m=1}^{\infty} \frac{\gamma^m}{1 - \alpha q^m/t} dt.$$

Theorem 2 can be proved by replacing  $F_n(q)$  by  $G_n(q, \alpha, \gamma)$  in Lemmas.
